Advanced Computational Econometrics Chapter 2: Linear and quadratic classification

1 Classification of the default_credit_card data

The file default_credit_card.csv contains data about customers' default payments in Taiwan.

Attribute Information:

- Y: default payment (Yes = 1, No = 0).
- X1 : Amount of the given credit (NT dollar) : it includes both the individual consumer credit and his/her family (supplementary) credit.
- X2: Gender (1 = male; 2 = female).
- X3 : Education (1 = graduate school; 2 = university; 3 = high school; 4 = others).
- X4: Marital status (1 = married; 2 = single; 3 = others).
- X5 : Age (year).
- X6 X11 : History of past payment. We tracked the past monthly payment records (from April to September, 2005) as follows : X6 = the repayment status in September, 2005; X7 = the repayment status in August, 2005; . . .;X11 = the repayment status in April, 2005. The measurement scale for the repayment status is : -1 = pay duly; 1 = payment delay for one month; 2 = payment delay for two months; . . .; 8 = payment delay for eight months; 9 = payment delay for nine months and above.
- X12-X17: Amount of bill statement (NT dollar). X12 = amount of bill statement in September, 2005; X13 = amount of bill statement in August, 2005; . . .; X17 = amount of bill statement in April, 2005.
- X18-X23: Amount of previous payment (NT dollar). X18 = amount paid in September, 2005; X19 = amount paid in August, 2005; . . .; X23 = amount paid in April, 2005.
- 1. Read the dataset default_credit_card.csv. Split the data into a training set of size 20,000 and a test set of size 10,000.
- 2. Build LDA, QDA, naive Bayes and logistic regression classifiers for these data. Print the confusion matrices and the test error rates.
- 3. Using function roc in package pROC, plot the ROC curves of the four classifiers built in the previous question.

2 Estimation of the Bayes error rate

We consider a classification problem with c=3 classes and p=2 predictors. The marginal distribution of Y is defined by the following prior probabilities:

$$\pi_1 = 0.3$$
, $\pi_2 = 0.3$, $\pi_3 = 0.4$,

and the conditional densities of **X** given Y = k, k = 1, 2, 3 are multivariate normal distributions $\mathcal{N}(\boldsymbol{\mu}_k, \boldsymbol{\Sigma}_k)$ with

$$\mu_1 = (0,0)^T, \quad \mu_2 = (0,2)^T, \mu_3 = (2,0)^T,$$

$$\Sigma_1 = \Sigma_2 = \Sigma_3 = \begin{pmatrix} 1 & 0.5 \\ 0.5 & 2 \end{pmatrix}$$

- 1. Estimate de Bayes error rate for this problem (use function dmvnorm of package mvtnorm to compute the density of the multivariate normal distribution.
- 2. Generate training datasets of different sizes, and compare the error probabilities of the LDA and QDA classifiers trained with this data to the Bayes error rate.

3 Ordinal regression

We consider again the Boston data set from the MASS package.

- 1. Define an ordinal variable medv_ord with three levels: low, medium and high by discretizing variable medv (median house value) using the 33% and 66% quantiles as cut-points.
- 2. Partition the Boston data set into a training set and a test set. Fit ordered logit and probit regression models on these data, with medv_ord as the response. Compute the test error rates and compare the results obtained by the two models. (Use a McNemar test).
- 3. Fit a multinomial logistic regression model of these data and compare the results with those obtained in the previous question.
