EM Algorithm

- An iterative optimization strategy motivated by a notion of missingness and by consideration of the conditional distribution of what is missing given what is observed.
- Can be very simple to implement. Can reliably find an optimum through stable, uphill steps.
- Difficult likelihoods often arise when data are missing. EM simplifies such problems.

(I) < ((()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) <

Notation

- Y : Observed variables
- Z : Missing or latent variables
- X : Complete data X = (Y, Z)
- $\boldsymbol{\theta}$: Unknown parameter

 $L(\theta)$: observed-data likelihood, short for $L(\theta; \mathbf{y}) = f(\mathbf{y}; \theta)$

 $L_c(oldsymbol{ heta})$: complete-data likelihood, short for $L(oldsymbol{ heta};oldsymbol{x})=f(oldsymbol{x};oldsymbol{ heta})$

 $\ell({m heta}), \ell_c({m heta})$: observed and complete-data log-likelihoods

Notation

- Suppose we seek to maximize $L(\theta)$ with respect to θ .
- Define $Q(\theta, \theta^{(t)})$ to be the expectation of the complete-data log-likelihood, conditional on the observed data $\mathbf{Y} = \mathbf{y}$. Namely

$$Q(\theta, \theta^{(t)}) = \mathbb{E}_{\theta^{(t)}} \{ \ell_c(\theta) \mid \mathbf{y} \}$$

= $\mathbb{E}_{\theta^{(t)}} \{ \log f(\mathbf{X}; \theta) \mid \mathbf{y} \}$
= $\int [\log f(\mathbf{x}; \theta)] f(\mathbf{z} | \mathbf{y}; \theta^{(t)}) d\mathbf{z}$

where the last equation emphasizes that Z is the only random part of X once we are given Y = y.

Description

The EM Algorithm

Start with $\theta^{(0)}$. Then

- **1** E step: Compute $Q(\theta, \theta^{(t)})$.
- **2** M step: Maximize $Q(\theta, \theta^{(t)})$ with respect to θ . Set $\theta^{(t+1)}$ equal to the maximizer of Q.
- Return to the E step unless a stopping criterion has been met; e.g.,

$$\ell(\boldsymbol{\theta}^{(t+1)}) - \ell(\boldsymbol{\theta}^{(t)}) \leq \epsilon$$

Convergence of the EM Algorithm

- It can be proved that $L(\theta)$ increases after each EM iteration, i.e., $L(\theta^{(t+1)}) \ge L(\theta^{(t)})$ for t = 0, 1, ...
- Consequently, the algorithm converges to a local maximum of $L(\theta)$ if the likelihood function is bounded above.

Example: mixture of normal and uniform distributions

Let Y = (Y₁,..., Y_n) be an i.i.d. sample from a mixture of a normal distribution N(μ, σ) and a uniform distribution U([-a, a]), with pdf

$$f(y;\theta) = \pi \phi(y;\mu,\sigma) + (1-\pi)c, \qquad (1)$$

where $\phi(\cdot; \mu, \sigma)$ is the normal pdf, $c = (2a)^{-1}$ is a known constant, π is the proportion of the normal distribution in the mixture and $\theta = (\mu, \sigma, \pi)^T$ is the vector of parameters.

- Typically, the uniform distribution corresponds to outliers in the data. The proportion of outliers in the population is then 1π .
- We want to estimate θ .

Observed and complete-data likelihoods

- Let Z_i = 1 if observation i is not an outlier, Z_i = 0 otherwise. We have Z_i ~ B(π).
- The vector $\boldsymbol{Z} = (Z_1, \ldots, Z_n)$ is the missing data.
- Observed-data likelihood:

$$L(\boldsymbol{\theta}) = \prod_{i=1}^{n} f(y_i; \boldsymbol{\theta}) = \prod_{i=1}^{n} [\pi \phi(y_i; \mu, \sigma) + (1-\pi)c]$$

• Complete-data likelihood:

$$L_{c}(\theta) = \prod_{i=1}^{n} f(y_{i}, z_{i}; \theta) = \prod_{i=1}^{n} f(y_{i}|z_{i}; \mu, \sigma) f(z_{i}|\pi)$$
$$= \prod_{i=1}^{n} \left[\phi(y_{i}; \mu, \sigma)^{z_{i}} c^{1-z_{i}} \pi^{z_{i}} (1-\pi)^{1-z_{i}} \right]$$

э

(I) < ((()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) <

Derivation of function Q

• Complete-data log-likelihood:

$$\ell_c(\boldsymbol{\theta}) = \sum_{i=1}^n z_i \log \phi(y_i; \mu, \sigma) + \left(n - \sum_{i=1}^n z_i\right) \log c + \sum_{i=1}^n \left(z_i \log \pi + (1 - z_i) \log(1 - \pi)\right)$$

• It is linear in the z_i . Consequently, the Q function is simply

$$Q(\theta, \theta^{(t)}) = \sum_{i=1}^{n} z_i^{(t)} \log \phi(y_i; \mu, \sigma) + \left(n - \sum_{i=1}^{n} z_i^{(t)}\right) \log c + \sum_{i=1}^{n} \left(z_i^{(t)} \log \pi + (1 - z_i^{(t)}) \log(1 - \pi)\right)$$

with $z_i^{(t)} = \mathbb{E}_{\theta^{(t)}}[Z_i|y_i].$

Description

EM algorithm

E-step: compute

$$z_i^{(t)} = \mathbb{E}_{\theta^{(t)}}[Z_i|y_i] = \mathbb{P}_{\theta^{(t)}}[Z_i = 1|y_i] \\ = \frac{\phi(y_i; \mu^{(t)}, \sigma^{(t)})\pi^{(t)}}{\phi(y_i; \mu^{(t)}, \sigma^{(t)})\pi^{(t)} + c(1 - \pi^{(t)})}$$

M-step: Maximize $Q(\theta, \theta^{(t)})$ We get

$$\pi^{(t+1)} = \frac{1}{n} \sum_{i=1}^{n} z_i^{(t)}, \quad \mu^{(t+1)} = \frac{\sum_{i=1}^{n} z_i^{(t)} y_i}{\sum_{i=1}^{n} z_i^{(t)}}$$
$$\sigma^{(t+1)} = \sqrt{\frac{\sum_{i=1}^{n} z_i^{(t)} (y_i - \mu^{(t+1)})^2}{\sum_{i=1}^{n} z_i^{(t)}}}$$

Bayesian posterior mode

- Consider a Bayesian estimation problem with likelihood $L(\theta)$ and priori $f(\theta)$.
- The posterior density if proportional to $L(\theta)f(\theta)$. It can also be maximized by the EM algorithm.
- The E-step requires

$$Q(\boldsymbol{\theta}, \boldsymbol{\theta}^{(t)}) = \mathbb{E}_{\boldsymbol{\theta}^{(t)}} \left\{ \ell_{c}(\boldsymbol{\theta}) \mid \mathbf{y} \right\} + \log f(\boldsymbol{\theta})$$

- The addition of the log-prior often makes it more difficult to maximize *Q* during the M-step.
- Some methods can be used to facilitate the M-step in difficult situations (see below).

Analysis

Overview

EM algorithm Analysis

Facilitating the M-step

SEM algorithm

・ロト ・聞ト ・ヨト ・ヨト

Why does it work?

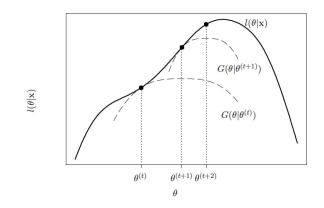

- Ascent: Each M-step increases the log likelihood.
- Optimization transfer:

$$\ell(heta) \geq Q(heta, heta^{(t)}) + \ell(heta^{(t)}) - Q(heta^{(t)}, heta^{(t)}) = G(heta, heta^{(t)}).$$

- The last two terms in $G(\theta, \theta^{(t)})$ do not depend on θ , so Q and G are maximized at the same θ .
- Further, G is tangent to ℓ at $\theta^{(t)}$, and lies everywhere below ℓ . We say that G is a minorizing function for ℓ .
- EM transfers optimization from ℓ to the surrogate function G, which is more convenient to maximize.

The nature of EM

One-dimensional illustration of EM algorithm as a minorization or optimization transfer strategy. Each E step forms a minorizing function *G*, and each M step maximizes it to provide an uphill step.

Analysis

Proof

We have

$$f(z|y;\theta) = \frac{f(x;\theta)}{f(y;\theta)} \Rightarrow f(y;\theta) = \frac{f(x;\theta)}{f(z \mid y;\theta)}$$

Consequently,

$$\ell(\theta) = \log f(y; \theta) = \underbrace{\log f(x; \theta)}_{\ell_c(\theta)} - \log f(z \mid y; \theta)$$

• Taking expectations on both sides wrt the conditional distribution of X given Y = y and using $\theta^{(t)}$ for θ :

$$\ell(heta) = Q(heta, heta^{(t)}) - \underbrace{\mathbb{E}_{ heta^{(t)}}[\log f(Z \mid y; heta) \mid y]}_{H(heta, heta^{(t)})}$$

(2)

17 / 42

Analysis

Proof - the minorizing function

• Now, for all $\theta \in \Theta$,

$$H(\theta, \theta^{(t)}) - H(\theta^{(t)}, \theta^{(t)}) = \mathbb{E}_{\theta^{(t)}} \left[\log \frac{f(Z \mid y; \theta)}{f(Z \mid y; \theta^{(t)})} \mid y \right]$$
(3a)
$$\leq \log \mathbb{E}_{\theta^{(t)}} \left[\frac{f(Z \mid y; \theta)}{f(Z \mid y; \theta^{(t)})} \mid y \right]$$
(*) (3b)
$$= \log \int f(z \mid y; \theta) dz = 0$$
(3c)

(*): from the concavity of the log and Jensen's inequality.

• Hence, for all $\theta \in \Theta$,

$$H(\theta, \theta^{(t)}) \le H(\theta^{(t)}, \theta^{(t)}) = Q(\theta^{(t)}, \theta^{(t)}) - \ell(\theta^{(t)}), \text{ or}$$

$$\ell(heta) \geq Q(heta, heta^{(t)}) + \ell(heta^{(t)}) - Q(heta^{(t)}, heta^{(t)}) = G(heta, heta^{(t)})$$

イロト イヨト イヨト イヨト

18 / 42

Proof - G is tangent to ℓ at $\theta^{(t)}$

• From (4),
$$\ell(\theta^{(t)}) = G(\theta^{(t)}, \theta^{(t)})$$
.

• Now, we can rewrite (4) as

$$Q(heta^{(t)}, heta^{(t)}) - \ell(heta^{(t)}) \geq Q(heta, heta^{(t)}) - \ell(heta), \quad orall heta$$

Consequently, $\theta^{(t)}$ maximizes $Q(\theta, \theta^{(t)}) - \ell(\theta)$, hence

$$Q'(heta, heta^{(t)})|_{ heta= heta^{(t)}}-\ell'(heta)|_{ heta= heta^{(t)}}=0$$

and

$$G'(\theta, \theta^{(t)})|_{\theta=\theta^{(t)}} = Q'(\theta, \theta^{(t)})|_{\theta=\theta^{(t)}} = \ell'(\theta)|_{\theta=\theta^{(t)}}.$$

・ロト ・聞ト ・ヨト ・ヨト

Analysis

Proof - monotonicity

• From (2),

$$\ell(\theta^{(t+1)}) - \ell(\theta^{(t)}) = \underbrace{Q(\theta^{(t+1)}, \theta^{(t)}) - Q(\theta^{(t)}, \theta^{(t)})}_{A} - \left[\underbrace{H(\theta^{(t+1)}, \theta^{(t)}) - H(\theta^{(t)}, \theta^{(t)})}_{B}\right]$$

- A ≥ 0 because θ^(t+1) is a maximizer of Q(θ, θ^(t)), and B ≤ 0 because, from (3), θ^(t) is a maximizer of H(θ, θ^(t)).
- Hence,

$$\ell(\theta^{(t+1)}) \ge \ell(\theta^{(t)})$$

Monte Carlo EM (MCEM)

- Replace the *t*-th E step with
 - Oraw missing datasets $\mathbf{Z}_{1}^{(t)}, \ldots, \mathbf{Z}_{m^{(t)}}^{(t)}$ i.i.d. from $f(\mathbf{z}|\mathbf{y}; \boldsymbol{\theta}^{(t)})$. Each $\mathbf{Z}_{j}^{(t)}$ is a vector of all the missing values needed to complete the observed dataset, so $\mathbf{X}_{j}^{(t)} = (\mathbf{y}, \mathbf{Z}_{j}^{(t)})$ denotes a completed dataset where the missing values have been replaced by $\mathbf{Z}_{j}^{(t)}$.
 - $\textbf{3} \quad \text{Calculate } \hat{Q}^{(t+1)}(\boldsymbol{\theta}, \boldsymbol{\theta}^{(t)}) = \frac{1}{m^{(t)}} \sum_{j=1}^{m^{(t)}} \log f(\mathbf{X}_j^{(t)}; \boldsymbol{\theta}).$
- Then $\hat{Q}^{(t+1)}(\theta, \theta^{(t)})$ is a Monte Carlo estimate of $Q(\theta, \theta^{(t)})$.
- The M step is modified to maximize $\hat{Q}^{(t+1)}(\boldsymbol{ heta}, \boldsymbol{ heta}^{(t)}).$
- Increase $m^{(t)}$ as iterations progress to reduce the Monte Carlo variability of \hat{Q} . MCEM will not converge in the same sense as ordinary EM, rather values of $\theta^{(t)}$ will bounce around the true maximum, with a precision that depends on $m^{(t)}$.

EM algorithm Description Analysis

Some variants Facilitating the E-step Facilitating the M-step

Variance estimation Louis' method SEM algorithm

・ロト ・聞ト ・ヨト ・ヨト

Facilitating the M-step

Generalized EM (GEM) algorithm

• In the original EM algorithm, $\theta^{(t+1)}$ is a maximizer of $Q(\theta, \theta^{(t)})$, i.e.,

$$Q(oldsymbol{ heta}^{(t+1)},oldsymbol{ heta}^{(t)})\geq Q(oldsymbol{ heta},oldsymbol{ heta}^{(t)})$$

for all θ .

However, to ensure convergence, we only need that

$$Q(\boldsymbol{\theta}^{(t+1)}, \boldsymbol{\theta}^{(t)}) \geq Q(\boldsymbol{\theta}^{(t)}, \boldsymbol{\theta}^{(t)})$$

• Any algorithm that chooses $\theta^{(t+1)}$ at each iteration to guarantee the above condition (without maximizing $Q(\theta, \theta^{(t)})$) is called a Generalized EM (GEM) algorithm.

EM gradient algorithm

- Replace the M step with a single step of Newton's method, thereby approximating the maximum without actually solving for it exactly.
- Instead of maximizing, choose:

$$egin{aligned} eta^{(t+1)} &= eta^{(t)} - \left. \mathbf{Q}''(m{ heta},m{ heta}^{(t)})^{-1}
ight|_{m{ heta} = m{ heta}^{(t)}} \left. \mathbf{Q}'(m{ heta},m{ heta}^{(t)})
ight|_{m{ heta} = m{ heta}^{(t)}} \ &= m{ heta}^{(t)} - \left. \mathbf{Q}''(m{ heta},m{ heta}^{(t)})^{-1}
ight|_{m{ heta} = m{ heta}^{(t)}} \, \ell'(m{ heta}^{(t)}) \end{aligned}$$

 Ascent is ensured for canonical parameters in exponential families. Backtracking can ensure ascent in other cases; inflating steps can speed convergence.

ECM algorithm

- Replaces the M step with a series of computationally simpler conditional maximization (CM) steps.
- Call the collection of simpler CM steps after the *t*-th E step a CM cycle. Thus, the *t*-th iteration of ECM is comprised of the *t*-th E step and the *t*-th CM cycle.
- Let S denote the total number of CM steps in each CM cycle.

ECM algorithm (continued)

For s = 1,..., S, the s-th CM step in the t-th cycle requires the maximization of Q(θ, θ^(t)) subject to (or conditional on) a constraint, say

$$\mathbf{g}_s(oldsymbol{ heta}) = \mathbf{g}_s(oldsymbol{ heta}^{(t+(s-1)/S)})$$

where $\theta^{(t+(s-1)/S)}$ is the maximizer found in the (s-1)-th CM step of the current cycle.

- When the entire cycle of S steps of CM has been completed, we set $\theta^{(t+1)} = \theta^{(t+S/S)}$ and proceed to the E step for the (t+1)-th iteration.
- ECM is a GEM algorithm, since each CM step increases Q.
- The art of constructing an effective ECM algorithm lies in choosing the constraints cleverly.

(I) < ((()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) <

Choice 1: Iterated Conditional Modes / Gauss-Seidel

- Partition θ into S subvectors, $\theta = (\theta_1, \dots, \theta_S)$.
- In the s-th CM step, maximize Q with respect to θ_s while holding all other components of θ fixed.
- This amounts to the constraint induced by the function

$$g_s(\theta) = (\theta_1, \ldots, \theta_{s-1}, \theta_{s+1}, \ldots, \theta_S).$$

Choice 2

- At the s-th CM step, maximize Q with respect to all other components of θ while holding θ_s fixed.
- Then $g_s(\theta) = \theta_s$.
- Additional systems of constraints can be imagined, depending on the particular problem context.
- A variant of ECM inserts an E step between each pair of CM steps, thereby updating Q at every stage of the CM cycle.

Overview

EM algorithm Description Analysis

Some variants Facilitating the E-step Facilitating the M-step

Variance estimation

Louis' method SEM algorithm

・ロト ・ 日 ・ ・ ヨ ・ ・ ヨ ・

Variance of the MLE

• Let $\hat{\theta}$ be the MLE of θ .

• As $n \to \infty$, the limiting distribution of $\hat{\theta}$ is $\mathcal{N}(\theta^*, I(\theta^*)^{-1})$, where θ^* is the true value of θ , and

$$I(\boldsymbol{ heta}) = \mathbb{E}_{\boldsymbol{ heta}}[\ell'(\boldsymbol{ heta})\ell'(\boldsymbol{ heta})^{\mathsf{T}}] = -\mathbb{E}_{\boldsymbol{ heta}}[\ell''(\boldsymbol{ heta})]$$

is the expected Fisher information matrix (the second equality holds under some regularity conditions).

- *I*(θ^{*}) can be estimated by *I*(θ̂), or by −ℓ''(θ̂) = *I*_{obs}(θ̂) (observed information matrix).
- Standard error estimates can be obtained by computing the square roots of the diagonal elements of $I_{obs}(\widehat{\theta})^{-1}$.

Obtaining variance estimates

- The EM algorithm allows us to estimate $\hat{\theta}$, but it does not directly provide an estimate of $I(\theta^*)$.
- Direct computation of $I(\widehat{\theta})$ or $I_{obs}(\widehat{\theta})$ is often difficult.
- Main methods:
 - Louis' method
 - Supplemented EM (SEM) algorithm
 - Sootstrap (to be studied in Chapter 6)

Missing information principle

We have seen that

$$f(\boldsymbol{z} \mid \boldsymbol{y}; \boldsymbol{\theta}) = rac{f(\boldsymbol{x}; \boldsymbol{\theta})}{f(\boldsymbol{y}; \boldsymbol{\theta})},$$

from which we get

$$\ell(\boldsymbol{\theta}) = \ell_c(\boldsymbol{\theta}) - \log f(\boldsymbol{z} \mid \boldsymbol{y}; \boldsymbol{\theta}).$$

• Differentiating twice and negating both sides, then taking expectations over the conditional distribution of **X** given **y**,

$$\underbrace{-\ell''(\boldsymbol{\theta})}_{\hat{\mathbf{i}}_{\mathsf{Y}}(\boldsymbol{\theta})} = \underbrace{\mathbb{E}\left[-\ell_{c}''(\boldsymbol{\theta}) \mid \mathbf{y}\right]}_{\hat{\mathbf{i}}_{\mathsf{X}}(\boldsymbol{\theta})} - \underbrace{\mathbb{E}\left[-\frac{\partial^{2}\log f(\mathbf{z} \mid \mathbf{y}; \boldsymbol{\theta})}{\partial \boldsymbol{\theta} \partial \boldsymbol{\theta}^{T}} \mid \mathbf{y}\right]}_{\hat{\mathbf{i}}_{\mathsf{Z}|\mathsf{Y}}(\boldsymbol{\theta})}$$

where

- $\hat{\imath}_{\mathsf{Y}}(\theta)$ is the observed information,
- $\hat{\imath}_{\mathsf{X}}(\theta)$ is the complete information, and
- $\hat{\imath}_{\mathsf{Z}|\mathsf{Y}}(\theta)$ is the missing information.

Thierry Denœux (UTC)

Louis' method

- Computing $\hat{\imath}_{\mathsf{X}}(\theta)$ and $\hat{\imath}_{\mathsf{Z}|\mathsf{Y}}(\theta)$ is sometimes easier than computing $-\ell''(\theta)$ directly
- We can show that

$$oldsymbol{\hat{\imath}}_{\mathsf{Z}|\mathsf{Y}}(oldsymbol{ heta}) = \mathsf{Var}[S_{\mathsf{Z}|\mathsf{Y}}(oldsymbol{ heta})],$$

where the variance is taken w.r.t. $\boldsymbol{Z}|\boldsymbol{y}$, and

$$S_{\mathsf{Z}|\mathsf{Y}}(\theta) = rac{\partial \log f(\mathbf{z} \mid \mathbf{y}; \theta)}{\partial \theta}$$

is the conditional score.

• As the expected score is zero at $\widehat{\theta}$, we have

$$\hat{\imath}_{\mathsf{Z}|\mathsf{Y}}(\widehat{\theta}) = \int S_{\mathsf{Z}|\mathsf{Y}}(\widehat{\theta}) S_{\mathsf{Z}|\mathsf{Y}}(\widehat{\theta})^{\mathsf{T}} \log f(z \mid \mathbf{y}; \widehat{\theta}) dz$$

36 / 42

Monte Carlo approximation

- When they cannot be computed analytically, $\hat{\imath}_{X}(\theta)$ and $\hat{\imath}_{Z|Y}(\theta)$ can sometimes be approximated by Monte Carlo simulation.
- Method: generate simulated datasets $x_j = (y, z_j), j = 1, ..., N$, where y is the observed dataset, and the z_j are imputed missing datasets drawn from $f(z|y; \theta)$
- Then,

$$\hat{\boldsymbol{\imath}}_{\mathbf{X}}(\boldsymbol{\theta}) pprox rac{1}{N} \sum_{j=1}^{N} - rac{\partial^2 \log f(\boldsymbol{x}_j; \boldsymbol{\theta})}{\partial \boldsymbol{\theta} \partial \boldsymbol{\theta}^T}$$

and $\hat{\imath}_{\mathsf{Z}|\mathsf{Y}}(\theta)$ is approximated by the sample variance of the values

$$\frac{\partial \log f(\boldsymbol{z}_j | \boldsymbol{y}; \boldsymbol{\theta})}{\partial \boldsymbol{\theta}}$$

(I) < ((()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) < (()) <

EM mapping

 $\bullet\,$ Let Ψ denotes the EM mapping, defined by

$$oldsymbol{ heta}^{(t+1)} = oldsymbol{\Psi}(oldsymbol{ heta}^{(t)})$$

• From the convergence of EM, $\widehat{\theta}$ is a fixed point:

$$\widehat{\boldsymbol{ heta}} = \boldsymbol{\Psi}(\widehat{\boldsymbol{ heta}}).$$

• The Jacobian matrix of $oldsymbol{\Psi}$ is the p imes p matrix

$$\mathbf{\Psi}'(oldsymbol{ heta}) = \left(rac{\partial \Psi_i(oldsymbol{ heta})}{\partial heta_j}
ight).$$

It can be shown that

$$\boldsymbol{\Psi}'(\widehat{\boldsymbol{\theta}})^{\mathsf{T}} = \boldsymbol{\hat{\imath}}_{\mathsf{Z}|\mathsf{Y}}(\widehat{\boldsymbol{\theta}})\boldsymbol{\hat{\imath}}_{\mathsf{X}}(\widehat{\boldsymbol{\theta}})^{-1}$$

Thierry Denœux (UTC)

EM algorithm

Using $\Psi'(\theta)$ for variance estimation

• From the missing information principle,

$$\begin{split} \mathbf{\hat{\imath}_{Y}}(\widehat{\theta}) &= \mathbf{\hat{\imath}_{X}}(\widehat{\theta}) - \mathbf{\hat{\imath}_{Z|Y}}(\widehat{\theta}) \\ &= \left[\mathbf{I} - \mathbf{\hat{\imath}_{Z|Y}}(\widehat{\theta})\mathbf{\hat{\imath}_{X}}(\widehat{\theta})^{-1} \right] \mathbf{\hat{\imath}_{X}}(\widehat{\theta}) \\ &= \left[\mathbf{I} - \mathbf{\Psi}'(\widehat{\theta})^{T} \right] \mathbf{\hat{\imath}_{X}}(\widehat{\theta}). \end{split}$$

Hence,

$$\hat{\imath}_{\mathbf{Y}}(\widehat{\theta})^{-1} = \hat{\imath}_{\mathbf{X}}(\widehat{\theta})^{-1} \left[\mathbf{I} - \mathbf{\Psi}'(\widehat{\theta})^{\mathsf{T}} \right]^{-1}$$

• From the equality

$$(I - P)^{-1} = (I - P + P)(I - P)^{-1} = I + P(I - P)^{-1},$$

we get

$$\hat{\imath}_{\mathbf{Y}}(\widehat{\theta})^{-1} = \hat{\imath}_{\mathbf{X}}(\widehat{\theta})^{-1} \left\{ \mathbf{I} + \mathbf{\Psi}'(\widehat{\theta})^T \left[\mathbf{I} - \mathbf{\Psi}'(\widehat{\theta})^T \right]^{-1} \right\}.$$

Thierry Denœux (UTC)

Estimation of $\Psi'(\widehat{oldsymbol{ heta}})$

• Ler r_{ij} be the element (i, j) of $\Psi'(\widehat{\theta})$. By definition,

$$r_{ij} = \frac{\partial \Psi_i(\widehat{\theta})}{\partial \theta_j}$$

= $\lim_{\theta_j \to \widehat{\theta}_j} \frac{\Psi_i(\widehat{\theta}_1, \dots, \widehat{\theta}_{j-1}, \theta_j, \widehat{\theta}_{j+1}, \dots, \widehat{\theta}_p) - \Psi_i(\widehat{\theta})}{\theta_j - \widehat{\theta}_j}$
= $\lim_{t \to \infty} \frac{\Psi_i(\theta^{(t)}(j)) - \Psi_i(\widehat{\theta})}{\theta_j^{(t)} - \widehat{\theta}_j} = \lim_{t \to \infty} r_{ij}^{(t)}$

where $\theta^{(t)}(j) = (\widehat{\theta}_1, \dots, \widehat{\theta}_{j-1}, \theta_j^{(t)}, \widehat{\theta}_{j+1}, \dots, \widehat{\theta}_p)$, and $(\theta_j^{(t)})$, $t = 1, 2, \dots$ is a sequence of values converging to $\widehat{\theta}_j$.

• Method: compute the $r_{ij}^{(t)}$, t = 1, 2, ... until they stabilize to some values. Then compute $\hat{\imath}_{\mathbf{Y}}(\hat{\theta})^{-1}$ using (5).

SEM algorithm

- **Q** Run the EM algorithm to convergence, finding $\widehat{\theta}$.
- ② Restart the algorithm from some $oldsymbol{ heta}^{(0)}$ near $\widehat{oldsymbol{ heta}}$. For $t=0,1,2,\dots$
 - Take a standard E step and M step to produce $\theta^{(t+1)}$ from $\theta^{(t)}$.

2 For
$$j = 1, ..., p$$

- Define θ^(t)(j) = (θ̂₁,..., θ̂_{j-1}, θ^(t)_j, θ̂_{j+1},..., θ̂_p), and treating it as the current estimate of θ, run one iteration of EM to obtain Ψ(θ^(t)(j)).
- Obtain the ratio

$$r_{ij}^{(t)} = \frac{\Psi_i(\boldsymbol{\theta}^{(t)}(j)) - \hat{\theta}_i}{\theta_j^{(t)} - \hat{\theta}_j}$$

for $i = 1, \dots, p$. (Recall that $\Psi(\widehat{\theta}) = \widehat{\theta}$.)

- **3** Stop when all $r_{ij}^{(t)}$ have converged
- The (i, j)th element of $\Psi'(\hat{\theta})$ equals $\lim_{t\to\infty} r_{ij}^{(t)}$. Use the final estimate of $\Psi'(\hat{\theta})$ to get the variance.
