```

## Exercise 1

As the density of  $\epsilon$  is symmetric, the MH ratio is the ratio of the densities at  $x^*$  and  $x^{(t-1)}$ , i.e., we have

$$R(x^{(t-1)}, x^*) = \frac{f(x^*)}{f(x^{(t-1)})} = \exp(|x^{(t-1)}| - |x^*|).$$

The following function `MH_Laplace` implements the random walk MH algorithm for this problem:

```
MH_Laplace <- function(N,sig){
  x<-vector(N,mode="numeric")
  x[1]<-rnorm(1,mean=0,sd=sig)
  for(t in (2:N)){
    epsilon<-rnorm(1,mean=0,sd=sig)
    xstar<-x[t-1]+ epsilon
    U<-runif(1)
    R<-exp(abs(x[t-1]) - abs(xstar))
    if(U <= R) x[t]<-xstar else x[t]<-x[t-1]
  }
  return(x)
}
```

Let us generate a sample of size  $10^5$  with  $\sigma = 10$ :

```
x<-MH_Laplace(100000,10)
```

The sample path and correlation plots show good mixing (the chain quickly moves away from its starting value, and the autocorrelation decreases quickly as the lag between iterations increases):

```
par(mfrow=c(2,1))
plot(x,type="l",xlab='t',ylab=expression(x[(t)]))
acf(x,lag.max=100)
```

Series x

Plot of the histogram with the Laplace density:

```
u<-seq(-10,10,0.01)
fu<-0.5*exp(-abs(u))
hist(x,freq=FALSE,ylim=range(fu))
lines(u,0.5*exp(-abs(u)))
```

Histogram of x

Let us now generate another sample of the same size, this time with  $\sigma = 0.1$ :

```
x<-MH_Laplace(100000,0.1)
```

This time, the sample path and correlation plots show poor mixing (the chain remains at or near the same value for many iterations, and the autocorrelation decays very slowly):

```
plot(x,type="l",xlab='t',ylab=expression(x[(t)]))
```

```
acf(x,lag.max=1000)
```

**Series x**

```
par(mfrow=c(1,1))
```

## Exercise 2

### Question a

The likelihood function is

$$L(\beta; y_1, \dots, y_n) = \prod_{i=1}^n \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{1}{2}(y_i - \beta x_i)^2\right) = (2\pi)^{-n/2} \exp\left(-\frac{1}{2} \sum_{i=1}^n (y_i - \beta x_i)^2\right).$$

The density of the Gamma distribution with shape parameter  $a$  and rate  $b$  is  $f(\beta) \propto \beta^{a-1} \exp(-b\beta)I(\beta > 0)$ . Here  $a = 2$  and  $b = 1$ , so  $f(\beta) \propto \beta \exp(-\beta)I(\beta > 0)$ . Consequently, the posterior density is

$$f(\beta | y_1, \dots, y_n) \propto \beta \exp(-\beta) \exp\left(-\frac{1}{2} \sum_{i=1}^n (y_i - \beta x_i)^2\right) I(\beta > 0).$$

### Question b

We first write a function that computes the likelihood:

```
loglik <- function(beta,x,y){
  n<- length(x)
  return(-0.5 * sum((y-beta*x)^2) - n/2*log(2*pi))
}
```

We then write a function that generates a MC of size  $N$  for a given data set:

```
gen_MH<-function(x,y,N){
  beta<-vector(N,mode="numeric")
  beta[1]<-rgamma(1,shape=2,rate=1)
  for(t in (2:N)){
    beta_star<-rgamma(1,shape=2,rate=1)
    u<-runif(1)
    logR <-loglik(beta_star,x,y)-loglik(beta[t-1],x,y)
    if( log(u) <= logR ) beta[t]<-beta_star else beta[t]<- beta[t-1]
  }
  return(beta)
}
```

### Question c

Data generation:

```
beta0<- rgamma(1,shape=2,rate=1)
n<-50
x<-rnorm(n)
y<-x*beta0+rnorm(n)
```

Plot of the data:

```
plot(x,y)
abline(0,beta0)
```

Running the MH algorithm:

```
N<-100000
beta<-gen_MH(x,y,N)
```

### Question d

Sample path:

```
plot(beta,type="l",xlab="iterations")
```

Histogram (leaving out the first 500 values):

```
hist(beta[500:N], xlab=expression(beta))
```

Autocorrelation plot:

```
acf(beta, lag.max=200)
```

### Series beta

### Question e

We use the batch means method. We first determine the lag  $k_0$  such that the autocorrelation is small enough to be neglected:

```
ACF<-acf(beta, lag.max=200, plot=FALSE)
k0<-ACF$lag[min(which(abs(ACF$acf)<0.01))]
```

We fix the burn-in period and we compute the number of batches:

```
D<-1000 # burn in
B<-floor((N-D)/k0)
```

We compute the means within each block:

```
Z<-vector(B, mode="numeric")
for(b in (1:B)) Z[b]<-mean(beta[(D+(b-1)*k0+1):(D+b*k0)])
```

The estimated simulation standard error is the standard deviation of the batch means divided by the square root of the number of batches:

```
se <- sd(Z)/sqrt(B)
```

Estimated posterior expectation of  $\beta$  and simulation standard error:

```
print(c(mean(beta[(D+1):N]), se), 3)
```

```
## [1] 1.01312 0.00123
```

## Exercise 3

### Question a

```
coal <- read.table("/Users/Thierry/Documents/R/Data/Compstat/coal.dat",header=TRUE)
plot(coal)
```

### Question b

The likelihood function is

$$L(\theta_1, \theta_2, k | \mathbf{x}) \propto \prod_{i=1}^k e^{-\theta_1} \theta_1^{x_i} \prod_{i=k+1}^n e^{-\theta_2} \theta_2^{x_i}.$$

We obtain the posterior distribution by multiplying the likelihood and the prior:

$$f(\theta_1, \theta_2, k | \mathbf{x}) \propto \underbrace{\theta_1^{\alpha_{01}-1} e^{-\beta_{01}\theta_1}}_{f(\theta_1)} \underbrace{\theta_2^{\alpha_{02}-1} e^{-\beta_{02}\theta_2}}_{f(\theta_2)} \underbrace{\prod_{i=1}^k e^{-\theta_1} \theta_1^{x_i} \prod_{i=k+1}^n e^{-\theta_2} \theta_2^{x_i}}_{L(\theta_1, \theta_2, k | \mathbf{x})}.$$

Now,

$$\begin{aligned} f(\theta_1 | \theta_2, k, \mathbf{x}) &\propto f(\mathbf{x} | \theta_2, k, \theta_1) f(\theta_1 | \theta_2, k) \\ &\propto L(\theta_1, \theta_2, k | \mathbf{x}) f(\theta_1) \\ &\propto \theta_1^{\alpha_{01}-1} e^{-\beta_{01}\theta_1} \prod_{i=1}^k e^{-\theta_1} \theta_1^{x_i} \prod_{i=k+1}^n e^{-\theta_2} \theta_2^{x_i} \\ &\propto \theta_1^{\alpha_{01} + \sum_{i=1}^k x_i - 1} \exp(-(\beta_{01} + k)\theta_1). \end{aligned}$$

Consequently,

$$f(\theta_1 | \theta_2, k, \mathbf{x}) = f(\theta_1 | k, \mathbf{x}) \sim G(\alpha_{01} + \sum_{i=1}^k x_i, \beta_{01} + k).$$

Symmetrically, we obtain in the same way

$$f(\theta_2 | \theta_1, k, \mathbf{x}) = f(\theta_2 | k, \mathbf{x}) \sim G(\alpha_{02} + \sum_{i=k+1}^n x_i, \beta_{02} + k).$$

Finally, the conditional probability mass function of  $k$  is

$$\begin{aligned} f(k | \theta_1, \theta_2, \mathbf{x}) &\propto f(\mathbf{x} | k, \theta_1, \theta_2) f(k | \theta_1, \theta_2) \\ &\propto L(\theta_1, \theta_2, k | \mathbf{x}) \\ &\propto \exp[k(\theta_2 - \theta_1)] \left(\frac{\theta_1}{\theta_2}\right)^{\sum_{i=1}^k x_i}. \end{aligned}$$

### Question c

The following function implements the Gibbs algorithm for this problem:

```
gibbs<-function(x,N,alpha10,beta10,alpha20,beta20){
  n<-length(x)
  # Initialization
  theta1 <- vector(length=N,mode="numeric")
  theta2 <- vector(length=N,mode="numeric")
  k <- vector(length=N,mode="numeric")
  p<-vector(length=n,mode="numeric")
  # First cycle
  # Sampling of k[1] from a uniform distribution
  k[1]<-sample(n,size=1)
  theta1[1]<-rgamma(1,shape=alpha10+sum(x[1:k[1]]),rate=beta10+k0)
  theta2[1]<-rgamma(1,shape=alpha20+sum(x[(k[1]+1):n]),rate=beta20+n-k0)
  for(t in (2:N)){
    # Conditional pmf of k
    for (j in (1:n)){
      p[j]<- (theta1[t-1]/theta2[t-1])^sum(x[1:j]) * exp(j*(theta2[t-1]-theta1[t-1]))
    }
    p<-p/sum(p)
    k[t]<- sample(n,size=1,prob=p)
    theta1[t]<-rgamma(1,shape=alpha10+sum(x[1:k[t]]),rate=beta10+k[t])
    theta2[t]<-rgamma(1,shape=alpha20+sum(x[(k[t]+1):n]),rate=beta20+n-k[t])
  }
  return(list(k=k,theta1=theta1,theta2=theta2))
}
```

We can run this algorithm on the data:

```
N<-10000
alpha10<-0.5
alpha20<-0.5
beta10<-1
beta20<-1
par<-gibbs(x=coal$disasters,N,alpha10,beta10,alpha20,beta20)
```

## Question d

Plots for  $\theta_1$ :

```
plot(par$theta1,type="l")
```

```
hist(par$theta1)
```

### Histogram of par\$theta1

```
acf(par$theta1)
```

### Series par\$theta1

Plots for  $\theta_2$ :

```
plot(par$theta2,type="l")
```

```
hist(par$theta2)
```

**Histogram of par\$theta2**

```
acf(par$theta2)
```

**Series par\$theta2**

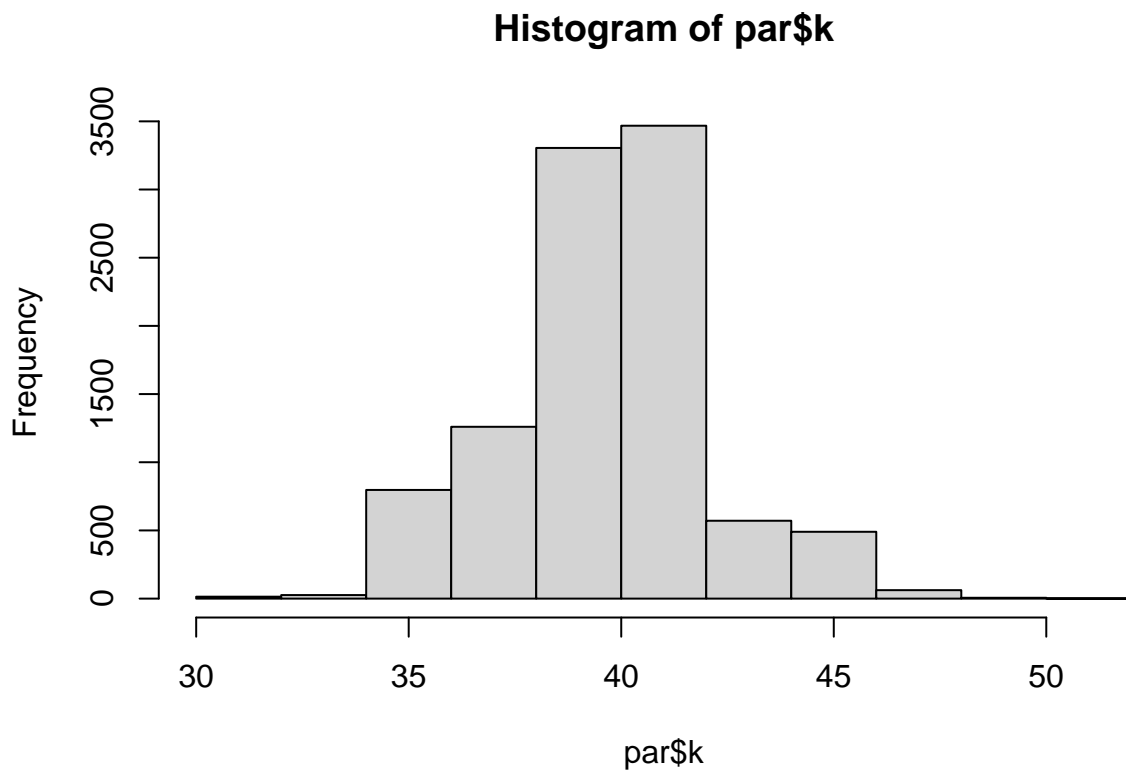

Plots for *k*:

```
plot(par$k, type="l")
```

```
hist(par$k)
```

```
acf(par$k)
```

## Series par\$k

### Question e

We set the lag to 10 and the burn-in period to 1000, and we compute the number  $N_1$  of batches:

```
L<-10 # lag
B<-1000 # burn in
N1<-floor((N-B)/L) # number of batches
```

Estimated conditional expectation and simulated standard error for  $\theta_1$ :

```
Z<-vector(N1,mode="numeric")
for(b in (1:N1)) Z[b]<-mean(par$theta1[(B+(b-1)*L+1):(B+b*L)])
se <- sd(Z)/sqrt(N1)
print(c(mean(par$theta1[(B+1):N]),se))
```

```
## [1] 3.051553433 0.003175602
```

Estimated conditional expectation and simulated standard error for  $\theta_2$ :

```
for(b in (1:N1)) Z[b]<-mean(par$theta2[(B+(b-1)*L+1):(B+b*L)])
se <- sd(Z)/sqrt(N1)
print(c(mean(par$theta2[(B+1):N]),se))
```

```
## [1] 0.914471335 0.001345767
```

Estimated conditional expectation and simulated standard error for  $k$ :

```
for(b in (1:N1)) Z[b]<-mean(par$k[(B+(b-1)*L+1):(B+b*L)])
se <- sd(Z)/sqrt(N1)
print(c(mean(par$k[(B+1):N]),se))
```

```
